Dear Governor Byrne:

Inclosed is the Phase I Inspection Report for Mine Hill Reservoir Dam in Morris County, New Jersey which has been prepared under authorization of the Dam Inspection Act, Public Law 92-367. A brief assessment of the dam's condition is given in the front of the report.

Based on visual inspection, available records, calculations and past operational performance, Mine Hill Reservoir Dam, initially listed as a high hazard potential structure, but reduced to a significant hazard potential structure as a result of this inspection, is judged to be in fair overall condition. The dam's spillway is considered inadequate because a flow equivalent to 3 percent of the Spillway Design Flood - SDF - would cause the dam to be overtopped. (The SDF, in this instance, is one half of the Probable Maximum Flood). To ensure adequacy of the structure, the following actions, as a minimum, are recommended:

- a. The spillway's adequacy should be determined by a qualified professional consultant engaged by the owner using more sophisticated methods, procedures and studies within six months from the date of approval of this report. Within three months of the consultant's findings remedial measures to ensure spillway adequacy should be initiated.
- b. Within one year from the date of approval of this report the owner should engage a qualified professional consultant to perform the following:
- (1) Design and oversee repairs for the eroded areas on the downstream slope and adjacent to the principal spillway wingwalls.
- (2) Design and oversee procedures for the removal of trees from the slope downstream of the dam for a distance of about 25 feet or to the property line, whichever is less, from the downstream face of the concrete capping on to the right of the emergency spillway.
- (3) Investigate the minor seepage at the left abutment of the dam and design and oversee required corrective measures.

APPROVED FOR PUBLIC RELEASE, DISTRIBUTION UNLIMITED.

NAPEN-N

Honorable Brendan T. Byrne

- (4) Design necessary remedial measures to prevent undermining of the downstream principal spillway apron by flow in the spillway channel downstream from the spillway.
- (5) Design and oversee repairs to the concrete principal spillway training walls.
- (6) Relocate the gate valves on the 10-inch water supply and draw-down lines to place them at or near the inlets on the upstream side of the dam.
- c. Within one year from the date of approval of this report the following remedial actions should be initiated:
- (1) Cut small trees growing in the stone masonry wall on the downstream face of the dam.
 - (2) Repair service bridge.
 - (3) Repair stoplog and supports.
 - (4) Repair concrete spalling on numerous surfaces on the dam.
 - (5) Replace concrete joint filler.
- d. The owner should develop written operating procedures and a periodic maintenance plan to ensure the safety of the dam, within one year from the date of approval of this report.
- e. An emergency action plan and warning system should be developed which outlines actions to be taken by the owner to minimize the downstream effects of an emergency at the dam within six months from the date of approval of this report.

A copy of the report is being furnished to Mr. Dirk C. Hofman, New Jersey Department of Environmental Protection, the designated State Office contact for this program. Within five days of the date of this letter, a copy will also be sent to Congressman Courter of the Thirteenth District. Under the provision of the Freedom of Information Act, the inspection report will be subject to release by this office, upon request, five days after the date of this letter.

Additional copies of this report may be obtained from the National Technical Information Services (NTIS), Springfield, Virginia 22161 at a reasonable cost. Please allow four to six weeks from the date of this letter for NTIS to have copies of the report available.

NAPEN-N

Honorable Brendan T. Byrne

An important aspect of the Dam Inspection Program will be the implementation of the recommendations made as a result of the inspection. We accordingly request that we be advised of proposed actions taken by the State to implement our recommendations.

Sincerely,

Incl

As stated

ROGER L. BALDWIN

Lieutenant Colonel, Corps of Engineers Commander and District Engineer

Copies furnished:

Mr. Dirk C. Hofman, P.E., Deputy Director Division of Water Resources N.J. Dept. of Environmental Protection P.O. Box CN029 Trenton, NJ 08625

Mr. John O'Dowd, Acting Chief Bureau of Flood Plain Regulation Division of Water Resources N.J. Dept. of Environmental Protection P.O. Box CN029 Trenton, NJ 08625

MINE HILL RESERVOIR DAM (NJ00777)

CORPS OF ENGINEERS ASSESSMENT OF GENERAL CONDITIONS

This dam was inspected on 21 April 1981 by Anderson-Nichols and Co. Inc., under contract to the State of New Jersey. The State, under agreement with the U.S. Army Engineer District, Philadelphia, had this inspection performed in accordance with the National Dam Inspection Act, Public Law 92-367.

Mine Hill Reservoir Dam, initially listed as a high hazard potential structure, but reduced to a significant hazard potential structure as a result of this inspection, is judged to be in fair overall condition. The dam's spillway is considered inadequate because a flow equivalent to 3 percent of the Spillway Design Flood - SDF - would cause the dam to be overtopped. (The SDF, in this instance, is one half of the Probable Maximum Flood). To ensure adequacy of the structure, the following actions, as a minimum, are recommended:

- a. The spillway's adequacy should be determined by a qualified professional consultant engaged by the owner using more sophisticated methods, procedures and studies within six months from the date of approval of this report. Within three months of the consultant's findings remedial measures to ensure spillway adequacy should be initiated.
- b. Within one year from the date of approval of this report the owner should engage a qualified professional consultant to perform the following:
- (1) Design and oversee repairs for the eroded areas on the downstream slope and adjacent to the principal spillway wingwalls.
- (2) Design and oversee procedures for the removal of trees from the slope downstream of the dam for a distance of about 25 feet or to the property line, whichever is less, from the downstream face of the concrete capping on to the right of the emergency spillway.
- (3) Investigate the minor seepage at the left abutment of the dam and design and oversee required corrective measures.
- (4) Design necessary remedial measures to prevent undermining of the downstream principal spillway apron by flow in the spillway channel downstream from the spillway.
- (5) Design and oversee repairs to the concrete principal spillway training walls.
- (6) Relocate the gate valves on the 10-inch water supply and draw-down lines to place them at or near the inlets on the upstream side of the dam.
- c. Within one year from the date of approval of this report the following remedial actions should be initiated:
- (1) Cut small trees growing in the stone masonry wall on the downstream face of the dam.

- (2) Repair service bridge.
- (3) Repair stoplog and supports.
- (4) Repair concrete spalling on numerous surfaces on the dam.
- (5) Replace concrete joint filler.
- d. The owner should develop written operating procedures and a periodic maintenance plan to ensure the safety of the dam, within one year from the date of approval of this report.
- e. An emergency action plan and warning system should be developed which outlines actions to be taken by the owner to minimize the downstream effects of an emergency at the dam within six months from the date of approval of this report.

APPROVED:

ROGER L. BALDWIN

Lieutenant Colonel, Corps of Engineers

Commander and District Engineer

Date of Inspection

Mine Hill Reservoir Fed ID No. NJ00777 New Jersey Morris Mine Brook Delaware April 21, 1981

ASSESSMENT OF GENERAL CONDITIONS

Mine Hill Reservoir Dam is an 85-year old concrete and stone masonry dam in fair overall condition. It is small in size and has a significant hazard classification. There is some leakage from the dam, with spalling and cracking of the surface concrete. The principal spillway is a 12-foot stoplog weir, with uncontrolled discharge also occurring from an 8-inch pipe and a 12-foot overflow emergency spillway. The total ungated spillway capacity at the crest of the main dam embankment would pass less than 2 percent of the one-half probable maximum flood inflow hydrograph outflow. The spillway capacity of Mine Hill Reservoir Dam is inadequate.

It is recommended that the owner retain the services of a professional engineer, qualified in the design and inspection of dams, to accomplish the following tasks in the near future: investigate the adequacy of the spillway capacity and design and oversee remedial measures as needed; design and oversee repairs for the eroded areas on the downstream slope and near the spillway wingwalls; design and oversee procedures for the removal of trees from the slope downstream of the dam; investigate the minor seepage at the left abutment and design and oversee required corrective measures; design necessary remedial measures to prevent undermining of the downstream principal spillway apron; design and oversee repairs to the concrete principal spillway walls; and relocate the gate valves on the 10-inch water supply and draw-down lines to place them at or near the inlets on the upstream side of the dam. It is further recommended that the owner undertake the following as a part of operating and maintenance procedures. In the near future: develop written operating procedures and a periodic maintenance plan to ensure the safety of the dam; cut small

trees growing in the masonry wall on the dam's downstream face; repair the bridge to the masonry intake tower; repair the stoplogs and supports; repair the concrete spalling on the dam; and replace concrete joint filler.

ANDERSON-NICHOLS & COMPANY, INC.

Warren A. Guinan, P.E.

Project Manager

New Jersey No. 16848

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonable possible storm runoff), or fractions thereof. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY INSPECTION PROGRAM MINE HILL RESERVOIR DAM FED ID NO. #NJ00777

SECTION 1 PROJECT INFORMATION

1.1 General

- a. Authority. Authority to perform the Phase I Safety Inspection of Mine Hill Reservoir Dam was received from the State of New Jersey, Department of Environmental Protection, Division of Water Resources by letter dated 12 December 1980 under Basic Contract No. FPM-39 and Contract No. A01093 dated 10 October 1979. This Authority was given pursuant to the National Dam Inspection Act, Public Law 92-367 and by agreement between the State and the U.S. Army Engineers District, Philadelphia. The inspection discussed herein was performed by Anderson-Nichols & Company, Inc.
- b. <u>Purpose</u>: The purpose of the Phase I Investigation is to develop an assessment of the general conditions with respect to the safety of Mine Hill Reservoir Dam and appurtenances. Conclusions are based upon available data and visual inspection. The results of this inspection are used to determine any need for emergency measures and to conclude whether or not additional studies, investigations, and analyses are necessary and warranted.

1.2 Project Description

a. Description of Dam and Appurtenances. Mine Hill Reservoir Dam (known locally as Lower Mine Hill Reservoir Dam) is a granite masonry structure with a concrete upstream facing and cap. The dam crest varies in elevation, and is about 27 feet above the low point on dam's toe. The principal spillway is a 12-foot long stoplog weir on the right (north) end of the dam. There is also an open 8-inch transite pipe in the dam's crest, with its invert slightly lower than the crest of the stoplogs. The emergency spillway is a 12-foot long notch in the dam's crest, only slightly lower than the crest. The total length of the dam and spillways is about 310 feet.

Two 10-inch gated pipes in the reservoir can be used as low-level outlets. One of the pipes is located at the base of a 13.2 foot diameter masonry tower located in the reservoir. The inlet to the other pipe is in the upstream face of the dam. The pipes are controlled by valves located on the downstream slope of the dam. One of these pipes leads to the Hackettstown Municipal Utility Authority's water treatment plant, while the other is for use as a blow-off line. These pipes are interconnected near the valve box.

- b. Location. The Dam is located in Mount Olive Township, New Jersey, on Mine Brook. It is about 1 mile east of the City of Hackettstown, east of Route 46 on an unimproved road. The dam is at 400 50.5' north latitude and 740 48.0' west longitude on the Hackettstown U.S. Geological Survey Quadrangle Map. A location map is included as Figure 2.
- c. Size Classification. Mine Hill Reservoir Dam is classified as being small in size on the basis of storage at the dam crest of 35.3 acre-feet, which is less than 1000 acre-feet, and on the basis of its structural height of 30 feet, which is more than 25 feet and less than 40 feet, in accordance with criteria given in the Recommended Guidelines for Safety Inspection of Dams.
- d. <u>Hazard Classification</u>. Visual inspection indicated that there are a group of houses on Mine Brook about 3400 feet downstream of the dam. In view of the potential for economic damage and the loss of few, if any lives, Mine Hill Reservoir Dam is classified as significant hazard.
- e. Ownership. Mine Hill Reservoir Dam is owned by the Hackettstown Municipal Utility Authority, P.O. Box 450, Hackettstown, New Jersey 08903. Mr. Joseph Richards can provide information about the dam, and can be reached at the above address.
- f. <u>Purpose</u>. Mine Hill Reservoir Dam is used as part of the water supply for the City of Hackettstown, New Jersey.
- g. Design and Construction History. The original plans and design notes for Mine Hill Dam, which was constructed in 1896, were not available. Repairs were made to the dam in 1943-44 and again in 1964 (See Appendix 4).
- h. Normal Operation Procedure. Mine Hill Reservoir Dam is operated for water supply, with one of the two 10-inch gated pipes used to convey water to a 1.0 MGD treatment plant as needed. Mr. Joseph Richards of the Hackettstown Municipal Utility Authority stated that the Authority generally removes the stoplogs from the principal spillway prior to large storms to preserve water quality in the reservoir.
- i. Site Geology. No site specific geologic information (such as borings) was available at the time the dam was inspected. Information derived from the Geologic Map of New Jersey (Kummel and Lewis, 1912) indicates soils within the immediate site consist of ground moraine overlying bedrock. Bedrock was observed in sporadic outcrops at the left abutment during inspection of this dam. The previously mentioned map indicates that bedrock in this area consists of granitoid gneiss of Precambrian age.

1.3 Pertinent Data

a. Drainage Area

1.77 square miles

b. Discharge at Damsite (cfs)

Maximum flood at damsite - unknown

Total ungated spillway capacity at top of dam - 46 cfs
with stop logs in place; 238 cfs with stop logs removed

c. Elevation (ft. above NGVD)

Top of dam - 802.0

Spillway Design Flood (SDF) - 804.8

Normal pool (at time of inspection) - 800.5

Spillway crest - 800.7 invert of 8-inch pipe

- 801.0 crest of stoplogs, principal

spillway

- 798.4 principal spillway crest with

stoplogs removed

- 801.9 emergency spillway crest

Streambed at centerline of spillway - 775 (toe of dam below 8-inch AC pipe)

Maximum tailwater at emergency spillway - 778
(estimate)

d. Reservoir length (feet)

Maximum pool - 700 (estimated)

Spillway crest - 600 (estimated)

e. Storage (acre-feet)

Spillway crest - at 800.7 ft. = 31.9 - at 801.0 ft. = 32.7

Top of dam - at 802.0 ft. = 35.3

Test Flood (PMF) - at 804.8 ft. = 43

f. Reservoir Surface (acres)

Top of dam - 2.9

Emergency spillway crest - 2.9

Principal spillway crest - 2.9

g. Dam

Type - masonry and concrete

Length - 310.5 feet (includes spillways)

Height - 27 feet (hydraulic)

- 30 feet (structural)

Top width - ranges 3 to 10 feet

Side slopes - upstream vertical; downstream varies from 1H:3V to 2H:1V

Zoning - not applicable

Impervious core - unknown

Cutoff - unknown

Grout curtain - unknown

h. Principal Spillway and Ungated Pipe

		=
	Principal Spillway	8-Inch Pipe
Туре	Stoplog weir	8-inch AC (ungated)

D/S Channel	10" pipe to water treatment plant	Free outfall

SECTION 2 ENGINEERING DATA

2.1 Design

No original plans, hydraulic or hydrologic data for Mine Hill Reservoir Dam were found.

2.2 Construction

Mine Hill Reservoir Dam was originally constructed in 1896 with major repairs undertaken in 1943-44 and 1964. A letter report describing the repairs undertaken in 1964 was available in the files of the New Jersey Department of Environmental Protection. This report is included in Appendix 4, Engineering Data.

2.3 Operation

The Hackettstown Municipal Utility Authority uses the Mine Hill Reservoir for water supply and draws water according to need.

2.4 Evaluation

- a. Availability. A search of the New Jersey Department of Environmental Protection files revealed very little information. All available information was retrieved.
- b. Adequacy. The engineering data available on this dam, together with data from visual observations, was adequate to allow evaluation of the dam for this Phase I Inspection.

SECTION 3 VISUAL INSPECTION

3.1 Findings

a. Dam.

Small trees are growing in the vertical masonry wall near the downstream edge of the dam crest. A slight amount of seepage was noted between masonry blocks near the crest of the dam and at the contact of the dam with the left abutment. Seepage was clear with no evidence of suspended fines. An earth berm is located downstream of the vertical masonry wall. The berm extends from the low-level outlet on the left side of the dam to the right spillway channel. Extensive erosion has occurred along the contact between the berm and the vertical masonry wall. Numerous trees up to 10 inches in diameter have been planted on the downstream slope of the berm. Erosion gullies up to 3 feet deep have occurred on the downstream slope and adjacent to the left spillway wingwall. Flowing water associated with an 8-inches diameter pipe which extends from the upstream face of the dam and terminates at the downstream slope near the left spillway wingwall may have been responsible for erosion and sloughing of the downstream slope near the end of the left spillway wingwall.

Some cracking (1/8 inch wide) on the upstream gunite facing was noted. The concrete cap is spalled in an area near the service bridge and some of the joint filler is missing. The masonry mortar is generally cracked over the entire downstream face of the dam. There are numerous rusting steel rods protruding through the upstream face.

b. Appurtenant Structures

Gated Spillway

Considerable erosion has occurred along the floor of the spillway discharge channel. Seepage water is discharging near the end of the left spillway training wall. The water is clear with no evidence of suspended fines. Water flowing in the spillway discharge channel passes underneath the spillway apron through openings between the stones approximately 20 feet from the end of the apron.

The spillway channel walls on both sides, upstream and downstream of the stoplogs, are generally cracked and spalled. Continuous undermining of the concrete walls at the base was observed. The bottom of the channel is open stone which permits discharge water to infiltrate. The wooden stoplogs are badly deflected and the center support is bent.

2. Outlet Works

The valve boxes for the two 10-inch low-level outlet pipes were visible at the time of the inspection. Although the valves were not tested, Mr. Joseph Richards of the Hackettstown Municipal Utility Authority stated that they are in operating condition.

The main beams of the service bridge to the masonry tower are badly rusted and the wood deck is weathered.

c. Reservoir Area

The watershed above the lake is gently to steeply sloping. Slopes on the shore of the lake appear to be stable. No evidence of significant sedimentation was observed.

d. Downstream Channel

Erosion has occurred on the right and left banks of the channel immediately downstream of the end of the principal spillway apron for a distance of 100 to 200 feet. Numerous trees have fallen into the channel and the channel bottom is covered with debris and boulders.

SECTION 4 OPERATIONAL PROCEDURES

4.1 Procedures

The owner withdraws water from the reservoir as needed for municipal water supply. Water is withdrawn to Hackettstown's water filtration plant by a 10-inch pipe controlled by a valve on the downstream slope of the dam.

4.2 Maintenance of Dam

Mr. Joseph Richards of the Hackettstown Municipal Utility Authority stated that their engineer conducts annual inspections of the dam.

4.3 Maintenance of Operating Facilities

No formal maintenance procedures for the operating facilities were disclosed. The fact that the reservoir is used for water supply purposes requires the Authority to keep operating facilities functional.

4.4 Warning System

No description of any warning system was disclosed.

4.5 Evaluation of Operational Adequacy

The overall operation and maintenance procedures for the dam seemed adequate. The remedial measures described in Section 7.2 should be implemented as prescribed.

SECTION 5 HYDROLOGIC/HYDRAULIC

5.1 Evaluation of Features

- a. Design Data. Because no hydrologic or hydraulic data were revealed, an evaluation could not be performed.
 - b. Experience Data. No experience data were found.
- c. <u>Visual Inspections</u>. No evidence of past overtopping of the dam crest was noted. Owing to the extremely steep stream channel downstream of the dam, it does not appear likely that tailwater conditions would affect spillway outflow. Valving of the 10-inch CIPs is on the downstream side of the dam; because these are located in the embankment section, a rupture above the valves would wash out the embankment.
- d. Overtopping Potential. The hydraulic/hydrologic evaluation for the dam is based on a selected Spillway Design Flood (SDF) equal to one-half the Probable Maximum Flood (PMF) in accordance with the range of test floods given in the evaluation guidelines for dams classified as significant hazard and small in size. The PMF was determined by application of a 24-hour Probable Maximum Precipitation (PMP) of 23.2 inches to the SCS dimensionless unit hydrograph. Hydrologic computations are given in Appendix 3. The routed one-half PMF peak outflow from the reservoir is 3,548 cfs.

Water will rise to elevation 802.0, one foot above the principal spillway with stoplogs in place, before overtopping the low point on the crest of the major part of the dam. Under this head the project's ungated outflow capacity is 46 cfs, which is less than the selected SDF.

Flood routing calculations indicate that Mine Hill Reservoir Dam will be overtopped for 12.9 hours to a maximum depth of 2.8 feet under one-half PMF conditions. It is estimated that the emergency spillway can pass 2 percent of the Spillway Design Flood inflow hydrograph, which is one-half the Probable Maximum Flood, without overtopping the dam. If the stoplogs were removed, the spillway could pass about 238 cfs before being overtopped, which is still only 6 percent of the one-half PMF inflow hydrograph.

e. <u>Draw Down.</u> Assuming no inflow, the reservoir pool can be drawn down in about two days using the two 10-inch valved pipes which serve as low-level outlets. Thus the drawdown capacity of this dam is adequate.

SECTION 6 STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability

Small trees growing in the vertical masonry wall on the downstream face near the crest will cause continuing deterioration of that wall and may result in seepage or erosion problems.

Minor leakage through joints between masonry blocks on the downstream face could lead to stability problems.

The trees growing on the downstream berm may blow over and pull out their roots or they may die with the result that their roots rot. In either case, severe seepage and erosion problems could result if the roots extend between the masonry blocks of the downstream face. Erosion on the surface of the berm, if not controlled, could contribute to stability problems in the dam if significant portions of the berm are eroded away.

Minor seepage is occurring at the contact of the masonry dam and the left rock abutment could result in failure of the dam, if not controlled. Because of freezing and thawing action, such seepage, if not controlled, could result in a serious problem.

Erosion along the discharge channel apron may undermine the spillway apron and cause collapse of the spillway wingwalls.

Based on the visual inspection alone, it is not possible to determine the character of the dam and spillway foundations or the interior of the cross section of the downstream berm or the slope of the upstream side of the masonry stone wall. Therefore, it is not possible to evaluate the factor of safety of the dam against slope failure, sliding, or overturning.

6.2 Design and Construction Data

No design or construction data pertinent to the structural stability of the dam are available.

6.3 Operating Records

No operating records pertinent to the structural stability of the dam were available.

6.4 Post-Construction Changes

Repairs to the dam were carried out in 1943-1944 and again in 1964. In the 1940's, a gunite upstream facing was placed on the dam. In 1964, this gunite facing was replaced, and

pressure grouting used to replace old mortar in the masonry. A trench about 3 feet deep was dug along the base of the dam, the masonry was sealed and gunite facing applied; the trench was backfilled with mud from the reservoir bottom. (See Appendix 4.)

6.5 Seismic Stability

This dam is in Seismic Zone 1. According to the Recommended Guidelines, dams located in Seismic Zone 1 "may be assumed to present no hazard from earthquake provided static stability conditions are satisfactory and conventional safety margins exist." None of the visual observations made during the inspection are indicative of unstable conditions. However, because no data are available concerning the engineering properties of the embankment and foundation materials for this dam, is not possible to make an engineering evaluation of stability or the factor of safety under static conditions.

SECTION 7 ASSESSMENT, RECOMMENDATIONS/REMEDIAL MEASURES

7.1 Dam Assessment

- a. Condition. Mine Hill Reservoir Dam is 85 years old and in fair condition.
- b. Adequacy of Information. The information available is such that the assessment of the dam must be based primarily on the results of the visual inspection.
- c. Urgency. The recommendations made in 7.2.a and 7.2.b. should be implemented by the owner as prescribed.
- d. Necessity for Additional Data/Evaluation. The information available from the visual inspection is adequate to identify the potential problems which are listed in 7.2.a. These problems require the attention of a professional engineer who will have to make additional engineering studies to design or specify remedial measures to rectify the problems. If left unattended, the problems could lead to failure of the dam.

7.2 Recommendation/Remedial Measures

- a. Recommendations. The owner should retain a professional engineer qualified in the design and construction of dams to accomplish the following in the near future:
 - (1) Investigate the adequacy of the spillway capacity and design and oversee remedial measures as needed.
 - (2) Design and oversee repairs for the eroded areas on the downstream slope and adjacent to the principal spillway wingwalls.
 - (3) Design and oversee procedures for the removal of trees from the slope downstream of the dam for a distance of about 25 feet or to the property line, whichever is less, from the downstream face of the concrete capping on to the right of the emergency spillway.
 - (4) Investigate the minor seepage at the left abutment of the dam and design and oversee required corrective measures.
 - (5) Design necessary remedial measures to prevent undermining of the downstream principal spillway apron by flow in the spillway channel downstream from the spillway.

- (6) Design and oversee repairs to the concrete principal spillway training walls.
- (7) Relocate the gate valves on the 10-inch water supply and draw-down lines to place them at or near the inlets on the upstream side of the dam.

b. Operating and Maintenance Procedures. The owner should accomplish the following in the near future:

- (1) Develop written operating procedures and a periodic maintenance plan to ensure the safety of the dam.
- (2) Cut small trees growing in the stone masonry wall on the downstream face of the dam.
- (3) Repair service bridge.
- (4) Repair stoplog and supports.
- (5) Repair concrete spalling on numerous surface on the dam.
- (6) Replace concrete joint filler.

Gilman	Guinan	Murdock

Gilman/Murdock/Stone Recorder

CONCRETE/MASONRY DAMS .

VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECOMMENDATIONS
SEEPAGE OR LEAKAGE	Leakage observed between masonry stone near crest of dam in vicinity of left abutment. Slight seepage between upper masonry blocks.	Investigate seepage and take remedial action as needed.
STRUCTURE TO ABUTHENT/EMBANKMENT JUHCTIONS	Slight seepage at left abutment junction. Some erosion evident at junction of dam with both abutments.	Investigate seepage and take remedial action as needed.
DRAINS	None	
WATER PASSAGES	None	
FOURDATION	Dam appears to be founded on bedrock in the vicinity of left abutment.	

CONCRETE/MASONRY DAMS

VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECOMMENDATIONS
SUBFACE CRACKS CONCRETE SURFACES	Some cracking (1/8-inch) on u/s concrete gunite facing. Top concrete slab has some spalling near bridge to outlet work (depth = 3/4-inch). D/s masonry mortar is cracked and spalled in numerous places. There are numerous rusting steel rods protruding through u/s face.	Repair u/s cracking and top slab spalling.
STRUCTURAL CRACKING	None	
VERTICAL AND HORIZONTAL ALIGNMENT	Good, no visual indication of either horizontal or vertical movement.	
MCNOLITH JOINTS	Not applicable	
CONSTRUCTION JOINTS	Good, no indication of movement, some of elastic joint filler has been removed.	Replace damaged joint filler.
RAILINGS:	None	Appears to be a need of railing along top of dam.

GATED SPILLWAY

VISUAL EXAMINATION OF	OBSERVATIONS	REMARKS OR RECOMMENDATIONS
CONCRETE SILL	Fair condition, some surface spalling and erosion. Top of right abutment is badly spalled and cracked.	Repair deteriorated concrete.
APPROACH CHANNEL	Unobstructed concrete walls are cracked and spalled - both sides. Bottom of channel is covered with silt and debris.	Repair deterioration.
DISCHARGE CHANNEL	Debris and trees in upper portion. Both sides are cracked and spalled. Continuous undermining of concrete walls at base. Bottom of channel placed stone - water is entering	Repair undermining of concrete walls and spalling. Seal channel bottom.
BRIDGE AND PIERS	Spillway. Not applicable	
GATES AND OPERATION EQUIPMENT	Wood stop logs are deflected d/s. Center support pipe is bent downstream.	Repair center support. Replace stop log w/stiffer planks.

UNGATED SPILLWAY

REMARKS OR RECOMMENDATIONS Good condition - no deficiencies observed. Bedrock bottom - clear and very steep. OBSERVATIONS Debris in channel. VISUAL EXAMINATION OF DISCHARGE CHANNEL APPROACH CHANNEL CONCRETE WEIR

RIDGE AND PIERS OVER SPILLWAY

Not applicable

EMBANKMENT (Earth berm downstream of masonry stone section)

REMARKS OR RECOMMENDATIONS OBSERVATIONS VISUAL EXAMINATION OF

Mr. Robert L. Hardman, P. E. Chief, Bureau of Water Control State of New Jersey Department of Conservation and Economic Development P. O. Box 1390 Tranton, New Jersey 08625

Reference: Dam Application No. 356

Dear Mr. Hardman:

Lower Mine Hill Distributing Reservoir

In your letter of June 4, 1969, addressed to the Hackettstown Municipal Utilities Authority, it was reported that your records indicated that the original permit for the construction of Lower Mine Hill Distributing Reservoir was declared null and void by the Division on November 5, 1942. It was requested that as-built drawings and other engineering data explanatory of the design and construction methods used be submitted since the dam apparently was constructed without prior approval by the Division.

The Authority has reviewed their files and find no as-built drawings of this dam but there is correspondence and information in the files indicating that this reservoir was constructed in 1897. A copy of a letter dated May 12, 1961 from the Hackettstown Board of Water Commissioners to Mr. John Wyack, Secretary of the Water Policy and Sumply Council, states that the Mine Hill Reservoir was built in 1897 under a grant by the Legislature of 1869 - Page 1090 - Paragraph 4.

In other correspondence, we find reference to a charter granted to the Hackettstown Aqueduct Company, under Laws of 1853, Page 369, and also reference to enabling acts by which the private plant (Hackettstown Aqueduct Company) was taken over by the Town of Hackettstown. Once again the Laws 1869, Page 1090 are mentioned.

Further, the approved drawings dated 1933 and 1934 for Hackettstown Storage Reservoir - Dam Application No. 218 show the Lower Mine Hill Reservoir to be an existing reservoir.

Mr. Robert L. Hardman, P. E.

Page 2

In view of the apparent year of construction (1897), we wonder if this is the reason that there is no approval in your files for the construction of this reservoir.

In addition, the Authority's file contains a print dated July 31, 1940, showing proposed repairs to Lower Mine Hill Reservoir, said repairs consisting of a solid reinforced concrete facing to be installed on the upstream facing of the existing rubble masonry dam. These repairs were never made and we wonder if the permit declared null and void on November 5, 1942 were to cover the proposed repairs indicated on this print dated July 31, 1940.

In view of the apparent date of construction of this reservoir, and the fact that no record plans of the construction are in the Authority's file, we would appreciate your advice on whether any additional information is required beyond the Annual Report dated May 27, 1969, which was recently submitted.

Very truly yours,

ELSON T. KILLAM ASSOCIATES, INC.

Board of Water Commissioners of the Town of Hackettstown 315 Washington Street Hackettstown, New Jersey 07840

Gentlemen:

Subject: Inspection and Recommendations for Repair of Lower Nine Hill Reservoir Dam

This report is submitted to recap the events, inspections, and repair work connected with the resurfacing of the upstream face of the Lower Mine Hill Reservoir dam.

Repairs to the dam were felt necessary by the Board because of the observed leakage, particularly in the wintertime, of water through the dam structure. A contract was let by the Board to the McColl Gunite and Grouting Company to prepare the upstream surface of the dam by cleaning and raking out any cracks or poor joints and applying 2 inches of gunite over a steel mesh to the upstream face.

The existing surface course, consisting of a thin plastered or gunited covering, appeared from a visual observation in fairly sound condition, except for cracks along its surface, and it was anticipated that the above-mentioned repairs would adequately seal the upstream face from any further leakage.

The reservoir was drained on June 8, 1964, and after the contractor started the cleaning and preparatory work, the surface course, believed to be added to the dam in 1943-1944, was found to be loose and without proper adhesion to the dam proper. Upon removing this surface course, the contractor found the original mortar joints between the blocks of stone to be in very poor condition. Work was started at the top of the dam, and approximately onequarter of the upstream surface was exposed when the contractor notified the Board of the conditions found and asked the Board for a re-evaluation of the scope or extent of repairs felt necessary. The contractor felt that because of actual conditions found, the possible extent of repairs might exceed the original intent or scope of his contract. At this time, June 11, 1964, the Board, through Hr. Lester E. Kelley, requested an inspection of the dam to be made to evaluate the conditions found, and to make whatever recommendations were necessary concerning the scope of repair work required to place the dam in a sound, watertight condition.

On Friday, June 12, 1964, Mr. Bartholomew of our office made a visual inspection of the dam proper, accompanied by Mr. G. Powers of the Board, and reviewed with the contractor work done to date.

The surface course of the upper half of the upstream face had been cleaned and the joints raked out at this time. The contractor reported that up to that time all of the surface course was

removed readily and many of the stone joints were in such condition that removal of the original mortar was easily accomplished by hand tools as deep as 3 to 4 feet.

It was felt by all parties that more extensive repairs were necessary than originally contemplated and it was our recommendation that a structural consultant be retained to review the structural condition of the dam and make their recommendations concerning necessary repairs.

With approval of the Board, the firm of Woodward-Clyde-Sherard and Associates was engaged, and a visit to the site was made on June 16, 1954, by Mr. David Greer, a principal of the above-mentioned firm, Mr. Frank Filippone, a structural engineer with our firm, Mr. Bartholomew, Mr. McColl, the contractor doing the repair work, and Mr. G. Powers of the Board.

By this date, repairs had exposed most of the upstream face, and it was found that the lower half of the dam face was in much sounder condition than the upper half.

A visual inspection of the downstream face and the base of the dam revealed no visual unsound structural conditions. Mr. Green's report is included as an appendix to this report and reviews in more detail the findings of those present at the site visit.

Additional recommended repairs and maintenance procedures not mentioned in Mr. Green's report include the following:

- (1) Carry 3-inch gunite face to top of dam slab surface and provide a water seal between the two surfaces with a 1" x 1" waterproof material such as Igas.
- (2) Chip out and clean any surface cracks in the concrete top slabs of the dam and caulk with a waterproof seal.
- (3) Wrap the intake silo with silo tie rods at the water surface where the brick work is loose and apply steel mesh and 2 inches of gunite to the entire outer surface.
- (4) Maintenance procedures should include varying the water surface in the wintertime so as to prevent large thick ice formations and make prodigious use of wood beams to take up the expansion of whatever ice does form.
- paragraph 10, page 4, of Mr. Greer's report, it is our opinion that any substantial leakage under the dam would be a major concern of the structural stability of the dam proper and observations should be continually made for this condition. Since no leakage under the dam has been observed by the Board members or operating personnel to date and no apparent leakage or evidence of this type leakage was observed during our inspections, it was felt that the extreme expense of grouting or sealing the surrounding ground and dam base below ground level (estimated at several times the cost of the present repairs) was not warranted at this time. Also, the expense of such work would be the same at any later date except for the necessity of draining the reservoir.

ははいいとはいいというというというできた。

The recommendations set forth in Mr. Greer's report and those mentioned in our report were conveyed verbally to the Board through Mr. Kelley on the night of June 16, 1964.

In summation, it is felt that although the repair work recommended will substantially increase the cost originally contemplated by the Board for repairs to the dam, this work is felt required as a minimum in order to insure a substantial reduction in leakage. This report or any verbal reports to date by Mr. Greer or members of this firm are not meant to imply that the dam proper is structurally sound and stable as extensive testing and investigation would be necessary to determine this fact. However, from all visual observations and from the fact that the dam has been standing since its construction, believed to be in 1895, without any visual sign of movement, there is no reason to believe that the dam is unstable or subject to any serious movement. With the completion of the recommended repairs and the careful control of ice formations, the dam should be serviceable for many years and well worth the moneys spent for its upkeep and repair. It is felt that the dam is valuable and necessary to the water facilities, certainly worth keeping in good repair, and the Board is to be commended for taking this remedial action before more serious deterioration or damage develops.

Very truly yours,

ELSON T. KILLAM ASSOCIATES, INC.

Peter Homack

Attention: Mr. Mel. E. Bartholomew

Inspection of Masonry Dam Hackettstown Water Board

Gentlemen:

On Monday June 15 I was asked by Mr. Bartholomew of Elson T. Killam Associates, to examine a leaky masonry dam belonging to the Hackettstown, N.J. Water Board, which was then undergoing repairs by the McColl Gunite and Grouting Company, Inc. My commission, as stated to me by Mr. Bartholomew, was to examine the condition of the structure and the reservoir, to review the plans for repairs, to discuss with representatives of Elson T. Killam Associates any changes in or additions to the plans which might be suggested by my observations or which might be proposed at the time of the inspection; and to present in writing my opinion with respect to the plans and my recommendations for changes or additions thereto. This report records my observations, opinions, and recommendations.

The dam, which is about 25 feet in height, is constructed of large, very roughly shaped, blocks of stone (apparently mostly granitic gneiss). The stone is laid roughly in courses and was probably set in lime-sand mortar. Construction date was reported to me as "about 1895". Repairs to the upstream and downstream faces were made in 1943 - 1944 (as shown by dates scribed in the mortar), the repairs consisting mostly of replacement of missing or softened mortar by new portland cement mortar.

At the time of my inspection, workmen were chipping out the unsound mortar on the upstream face. Most of the remaining exposed portland cement mortar (presumed to be from the 1943-44 repairs) was hard and sound; but there were some soft spots remaining; there were many areas where this mortar was missing entirely, and an older mortar (presumably the original construction) was exposed; there were several areas where this older mortar was missing, so that a steel rule could be thrust into the space between the stones to distances which were reported to be as much as 4 feet (or between 1/3 and 1/2 the thickness of the dam at that point). In addition, there were numerous small holes through areas of sound portland cement mortar, evidently opening into mortarless spaces within the body of the dam.

The older mortar which was exposed was yellow in color, had the texture of a clayey or silty medium sand, and could be cut easily with a pen-knife in most places, and dug out with the fingers in many places.

The dam was reported to have been leaking badly, with several areas of concentrated flow from the downstream face. Although some specific flows were reported in the lower part, there was no report of under-seepage, or of water emerging from the stream bed downstream. It was stated that leakage in the upper part of the dam was especially conspicuous after ice had started to build up on the downstream face in the winter months, and the suggestion was made that the upper courses of stone were temporarily separated (or raised) by expansion of the internal ice lenses as they built up.

Examination of the concrete slab which forms the top surface of the dam showed a few cracks, at a right-angle to the axis of the dam, which were closed at the time of my inspection and which did not suggest that there had been much if any uplift of this slab due to ice action.

At the time of my inspection, the proposed repairs had progressed to the point where most of the unsound mortar exposed on the reservoir face of the dam had been chipped away by means of pneumatic hammers; and it was reported that the next step would be the cleaning of the exposed joints by jetting, preparatory to packing with mortar.

At my request, a test pit was dug by hand, at the base of the upstream face and about the center of the dam. The pit was entirely in a mass of rock chips in a matrix of clayey silt (sediment). Although the soil was saturated, and a trickle of water was flowing in a small surface channel two or three feet from the pit, there was almost no seepage into the pit, indicating that the soil at this point is relatively impervious. The mortar exposed by the pit appeared to be sound.

After some discussion, it was agreed that the Contractor would proceed with the repairs, with the following conditions:

- 1. Chipping and cleaning would proceed on the reservoir face of the dam as planned.
- 2. A trench, two to three feet deep, would be dug along the base of this face of the dam; and chipping and cleaning, as well as subsequent joint filling, guniting, etc., would be extended down into this trench.
- 3. Open pipes, for subsequent grout injection, would be set as far as possible into the open joints, and would be mortared into place. Spacing and size of these grout pipes would be left to the judgment of the Contractor.
- 4. Joints would be filled with portland cement mortar.
- 5. The gunite facing on the dam would be 3 inches thick, and would be reinforced by 3/8" bars on 18" centers, both horizontal and vertical.

- 6. The supporting pins for the reinforcing would be set (using lead) in holes drilled into sound rock, as nearly as practical on 3-foot centers. No pins would be supported in joint mortar, either old or new.
- 7. After the gunite facing had been completed, neat cement grout would be pumped into the dam through the grout pipes referred to in (3) above. The grouting pressure would be controlled carefully so as not to lift or move the stones comprising the dam; and grout injection would be stopped whenever grout began to emerge from the downstream face of the dam.
- 8. The trench referred to in (2) above would be backfilled, not with the stony soil that came out of it, but with mud from the reservoir bottom.
- 9: No pointing or guniting would be done on the downstream face of the dam.
- 10. As the reservoir is filled, careful observations would be made for possible leaks under the dam or through it below the mud line; and if such leaks should develop, the situation would be reviewed with a view to planning a foundation grouting program to be put into effect on the next occasion when the reservoir could be emptied.

These points represent my recollection of the steps agreed on in discussion between Mr. Bartholomew, Mr. Powers, and myself. I concur in all of them.

It has been a pleasure to be of service to you and the Hackettstown Water Board.

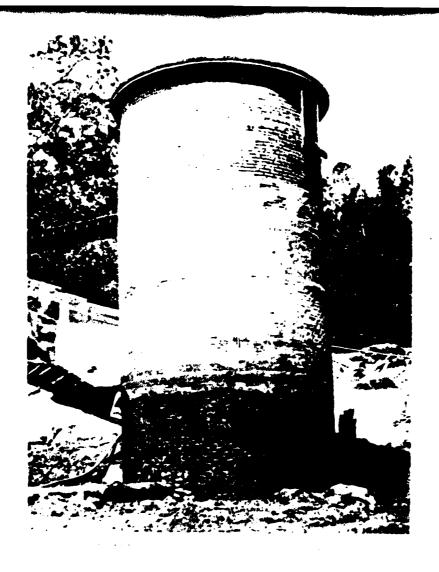

Very truly yours

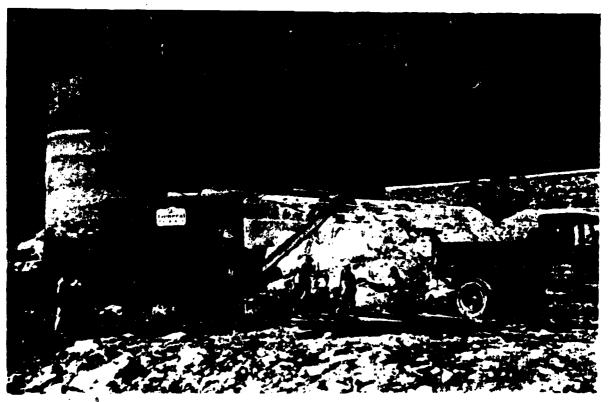

David M. Greer, P.E.
